

Machine learning

- Machine learning - field of study that gives computer ability to learn without being explicitly programmed

→ Traditional Programming Rule → [] → Answer

→ Machine learning Answer → [] → Rule
Data → [] → Rule

- why machine learning
 - do not require human experts
 - Black box human expertise (face, handwriting recognition)
 - Rapidly changing phenomenon (fraud detection)
 - Need for automation (Personalisation)

→ Machine learning Process flow

Training data → Learn Algorithm → Build model → Perform

Learning vs design -

- designer can help create data without noise leading to accurate machine learning model.
- designer helps machine learning gather better data.
- designer help set expectation and establish trust with user.
- designer specifically - UX can add clarity to ml powered interface.
- Machine learning customised interface to user needs.

→ Error - It measures how wrong was our estimation.

→ Noise - It refers to irrelevant information.

→ Training vs testing

- Training set - dataset that is feed to ML model so that it learns patterns and trends.
- Testing set - Once model is trained, we can make prediction on testing set.
- Validation set - Training set is divided into, train & validation set based on validation result, model is trained.

Machine learning will can

financial service (Fraud, Risk detection)
Healthcare (Disease prediction)
Agriculture
E-commerce (Recommendation)
Travel

Steps in ml

Import data → Prepare, clean data → Fit model → Evaluation new data
accuracy.

- Data acquisition - involves collecting and acquiring data from various sources like census data, log of servers.
- Data preparation - The data collected is not clean there are some errors which need to be cleaned.
- Hypothesis and modelling - based on requirement a model is created using dataset.
- Evaluation - Model is evaluated on test dataset.
- Deployment - In this model is deployed in market.
- operation & optimisation - Retraining of model.

Type of learning -
Supervised (labelled data)

Unsupervised (unlabelled data)

Reinforcement (Reward-based learning)

→ Supervised learning - Regression (Numerical prediction of continuous value)
Classification (prediction of categorical value)

Regression or linear regression vs classification - Decision tree
multiple linear regression

Random forest
Naive Bayes, SVM

→ Unsupervised learning - clustering - (finding groups)
Density estimation
Visualization.

clustering - means grouping objects based on similarity.

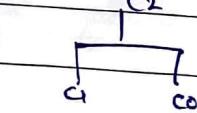

Ex - k-means clustering, c-means clustering, Hierarchical clustering

use - marketing, insurance, search engines, seismic zones.

Type - Exclusive clustering - independent clusters, no overlapping

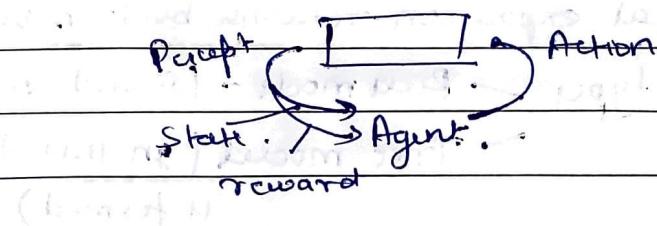

overlapping clustering - an item can belong to one or more clusters

Hierarchical → when two cluster have parent child relation.

computer

- Reinforcement learning - In this "agent" take action in environment in order to maximize the reward.

- Learning models of Geometric model

Probabilistic model

logical model

Geometric model - These model define similarity by considering the geometry of the instance (pace). Few feature could be points in two dimension (x and y axis) or in 3-dimension.

Geometric model are of two type - linear model

distance based model.

- Linear model - In linear models pth equation used.

$$g(n) = a + bn$$

Example - hour study vs marks

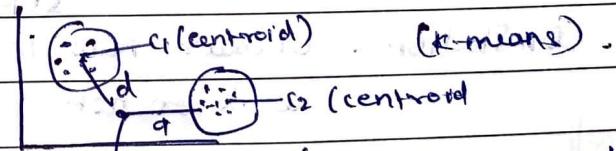

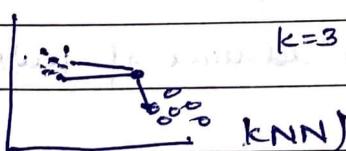

rainfall vs yield.

- Distance based model - In this model concept of distance is used for classification. Some algo based on these are -

→ Nearest neighbour classifier.

(Distance can be euclidean, manhattan etc.)

→ K-means clustering

- Probabilistic model - A probabilistic model is based on theory of probability. This model try to represent and manipulate the level of uncertainty.

Example - Naive bayes classifier. - It is based on the Naive bayes conditional Probability formula.

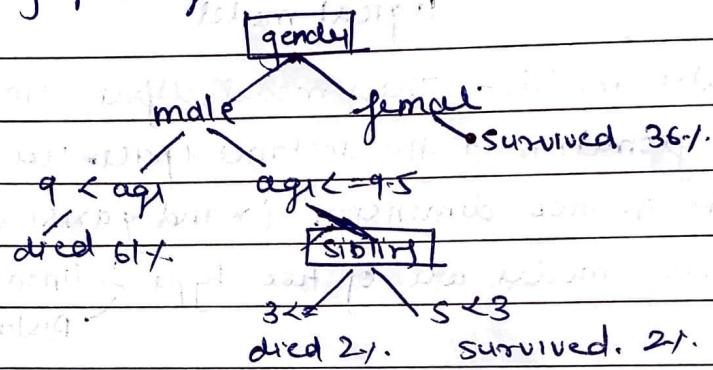

$$P(A|B) = \frac{P(B|A) P(A)}{P(B)}$$

→ logical learning models - logical model uses a logical expression to divide instance space into segments and construct grouping. A logical expression returns boolean values.

There are two types → Rule model - (Based on if then rule) → Tree model (in tree tree structure is formed).

Example of logical model - decision tree algo.

survival of passenger on titanic.

→ Feature - In training data we have matrix where each row is a vector and column is dimension we call each dimension a feature.

- feature selection - In very high dimensional data such as DNA and text document we need some important features, selecting those features is called feature selection.

- Methods - univariate → Pearson correlation, F-score, chi-square

multivariate - dimensionality reduction, SVM

- limitation - unclear how to tell in advance if feature will work or not

number of features - how many features to select.

Unit 2 classification and regression

- regression - numerical prediction of continuous value.

- classification - categorical prediction.

- linear regression - it is a supervised machine learning algorithm in this we predict y (dependent variable) based on given independent variable (x).

function →

$$y = \theta_0 + \theta_1 \cdot x$$

θ_1 - intercept θ_2 - coefficient of x .

Once we get θ_1 & θ_2 , we get best fit line. which is then used for further predictions.

$$y = \theta_1 + \theta_2 x$$

$$\theta_2 = \frac{\sum (x - \bar{x}) * (y - \bar{y})}{\sum (x - \bar{x})^2}$$

\bar{x} - mean.

$$\theta_1 = \text{constant} = \bar{y} = \theta_1 + \theta_2 \bar{x}$$

- find best fit line for given data

- prediction for unknown value

$$x \quad y \quad x - \bar{x} \quad y - \bar{y}$$

$$95 \quad 85 \quad 17 \quad 8 \quad \text{put in formula} -$$

$$85 \quad 78 \quad 7 \quad 18 \quad \theta_2 = 0.644$$

$$80 \quad 70 \quad 2 \quad 12 \quad \text{so } \theta_1 + 0.644 \times 2 = 70$$

$$70 = \theta_1 + 0.644 \times 2 \quad \theta_1 = 66.78$$

$$60 \quad 70 \quad -18 \quad 12 \quad 70 = \theta_1 + 0.644 \times 78$$

$$390 \quad 385 \quad \text{so } \theta_1 = 26.78$$

$$\text{Aug } 78 \quad 78 \quad \text{fitting eqn} = 26.78 + 0.644 x$$

- multiple linear regression - it involves more than one predictor variable.

$$\text{eqn} = Y = w_0 + w_1 x_1 + w_2 x_2 + w_3 x_3$$

- Non-linear regression - given that data is not linearly dependent so we need more accurate model. this can be achieved by non-linear regression.

$y = w_0 + w_1 x + w_2 x^2 + w_3 x^3$

- exponential regression - if there is constant rate change we use linear model but in constant percent rate of change exponential model is good. for example

$$f(x) = a * b^{x+1}$$

→ logistic regression - it's a supervised classification algorithm similar to linear regression but target value is discrete. It uses logistic function for classification of class or category.

$$f(m) = \frac{1}{1+e^{-k(m-n_0)}}$$

logistic funcⁿ

linear regression
Predicts continuous value

logistic regression
predict categorical value

→ Model performance

Model performance are metrics used to evaluate performance of machine learning model. These help in finding reliability and accuracy of model.

different metrics are -

- o) Accuracy - It is fraction of correctly classified sample out of total number of samples.
- o) Precision - Precision is fraction of true positive prediction out of all positive prediction. It predicts how many positive prediction made are actually true.
- o) Recall - It is fraction of true positive prediction out of all actual positive cases. It detect how well the model is able to detect positive case.
- o) F1 score - It is harmonic mean of precision and recall. It provides a single metric that balances precision & recall.
- o) Confusion matrix - A confusion matrix is a table that summarises performance of a binary classifier.
- o) Regression
- o) Mean absolute error - Average of absolute difference between predicted and actual value.
- o) Mean squared error - It is average squared difference b/w predicted and actual value.

confusion matrix Actual

		Actual	
		TN	FP
Actual	No.	FN	TP
	Yes.		

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

$$\text{F1 score} = \frac{2}{\text{Recall} + \text{Precision}}$$

- Overfitting - overfitting occurs when a model is too complex and has learned noise in the data instead of underlying relationship. As a result model performs well on training data but poorly on test data.
- Underfitting - it occurs when model is too simple and cannot capture underlying relationship. As a result model poorly performs on both training and test data.

- Bias - it refers to difference between predicted value and true value. A model with high bias consistently predicts same value than it because model is too simple and do not capture relationship in data. High bias lead to underfit and model is not able to fit to training data.
- Variance - it refers to variability of model's prediction for a given input. A model with high variance is sensitive to small fluctuation and produce very different prediction. It lead to overfitting when model become too complex and fits well on train set and poor on test set.

Reduce bias

- Increase model complexity
- Add more feature
- Increase train data
- Regularization

Reduce variance

- Simplify data
- Feature selection
- Early stopping
- Regularization

A good model have low bias and low variance.

- Generalization generalization is the model's ability to give sensible output to sets of input that has never seen before.
- generalization examine how well new data model can predict new data.
- A generalist model neither underfit or overfit.
- The theory of generalization is based on idea that the training data only provides limited samples of distribution and goal of ML model is to learn underlying pattern to make accurate prediction.
- Regularization - it is a method to avoid high variance and overfitting as well as to increase generalization.
- Regularization is process of shrinking or regularizing coefficient towards zero in this way it prevent learning of complicated model.
- It enhances generalization capabilities.
- Poor generalization is due to overfitting or underfitting.
- for poor generalization we apply regularization.
- L1 regularization also called lasso regularization. It adds a penalty term to the loss function that is proportional to ~~absolute value~~ of coefficient.

$$\text{cost} = \sum_{i=0}^N (y_i - \sum_{j=0}^M w_j w_j)^2 + \lambda \sum_{j=0}^M |w_j|$$

- L2 regularization, called ridge regularization, it add penalty term to loss function that is proportional to square of coefficient.

$$\text{cost} = \sum_{i=0}^N (y_i - \sum_{j=0}^M w_j w_j)^2 + \lambda \sum_{j=0}^M w_j^2$$

- L3 regularization - very less used in the penalty term to loss function is proportional to cube of coefficient.
